

# LockPeeker: Detecting Latent Locks in Java APIs

林子熠, 钟浩, 陈雨亭, 赵建军

上海交通大学, 日本九州大学

# Introduction

- It is a hot research topic to detect deadlocks.
  - Most approaches focus on analyzing developers' program.
- What if locks in APIs whose code is unavailable?
  - We refer such locks as latent locks.

# Motivating Example

```
public class SimpleBirt287102 {
    private SimpleClassLoader loader;
    private Object obj;

    class Thread1 extends Thread {
        public void run() {
            Class.forName("java.lang.Object", true, loader);
        }
    }

    class Thread0 extends Thread {
        public void run() {
            synchronized (obj) {
                Class.forName("java.lang.Object", true, loader);
            }
        }
    }

    class SimpleClassLoader extends ClassLoader {
        public Class<?> loadClass(String name) {
            synchronized (obj) { ... }
            return super.loadClass(name);
        }
    }

    private static native Class<?> forName0(String name,
        boolean initialize, ClassLoader loader, Class<?> caller);
```

``Thread-1":  
Waiting a latent lock here  
at java.lang.Class.forName0(Native Method)  
at java.lang.Class.forName(Class.java:348)  
at  
SimpleBirt287102\$Thread2.run(SimpleBirt287102.java:45)  
- locked <0x00000000d5eee710> (a java.lang.Object)

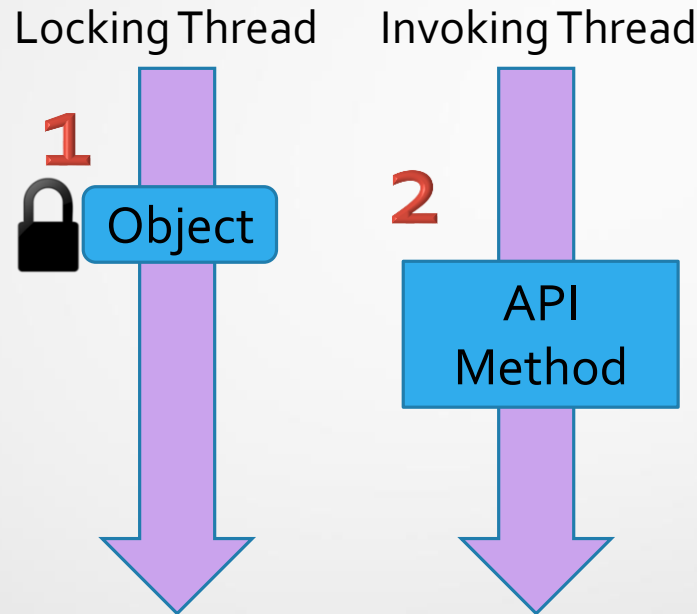

``Thread-0":  
at  
SimpleBirt287102\$SimpleClassLoader.loadClass(SimpleBirt287102.java:64)  
- waiting to lock <0x00000000d5eee710> (a java.lang.Object)  
Acquire a latent lock here  
at java.lang.Class.forName0(Native Method)  
at java.lang.Class.forName(Class.java:348)  
at  
SimpleBirt287102\$Thread1.run(SimpleBirt287102.java:33)

How to find the latent lock in this native method?

# Illustration of Idea

Locks in this paper are Java intrinsic locks, acquired by “synchronized” keyword

- Which object could be locked?
- How many locks in the API method?
- What are the relations among the locks?
- Are there any conditions for locking?

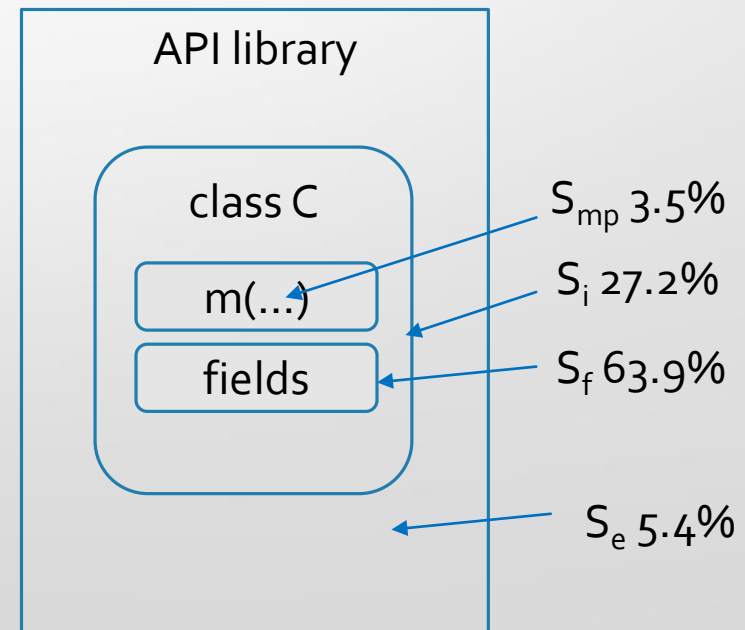

# Approach

- Select potential locking objects
- Design stateful lock tree model to represent the locking structure in the method
- Synthesize locking structure
- Synthesize conditions

# Selecting Locking Objects

- Investigate 1,414 locks inside methods from 10 open source projects
- For an API method  $m$  in class  $C$ , the locking objects are in 4 sets:
  - $S_{mp}$ : parameters of  $m$
  - $S_i$ : instance of  $C$  (this), or the class of  $C$  ( $C.class$ )
  - $S_f$ :  $C$ 's fields
  - $S_e$ : other objects from environment
- In this paper,  $S_c = S_{mp} + S_i + S_f$
- Primitive type objects are omitted

# Stateful Lock Tree

- Stateful lock tree (SLT) extends traditional lock tree to represent the locking structure in a method
  - Root denotes the API method
  - Test input values are stored in root
  - Node denotes lock
- Condition lock tree (CLT) adds condition in each node, denoting the condition to trigger the lock

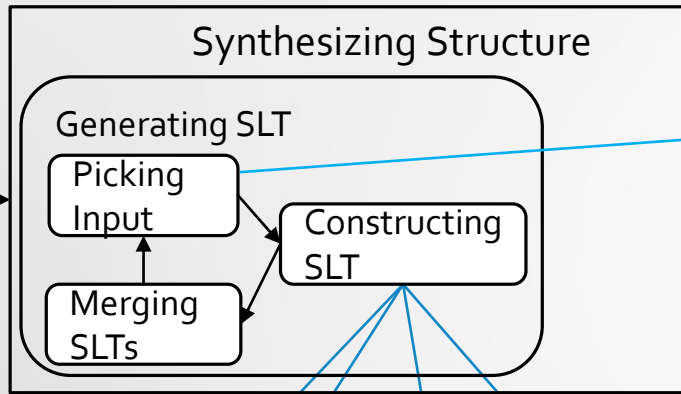

Test input values

```
synchronized(l1){...}  
synchronized(l2){  
    synchronized(l3){...}  
}
```

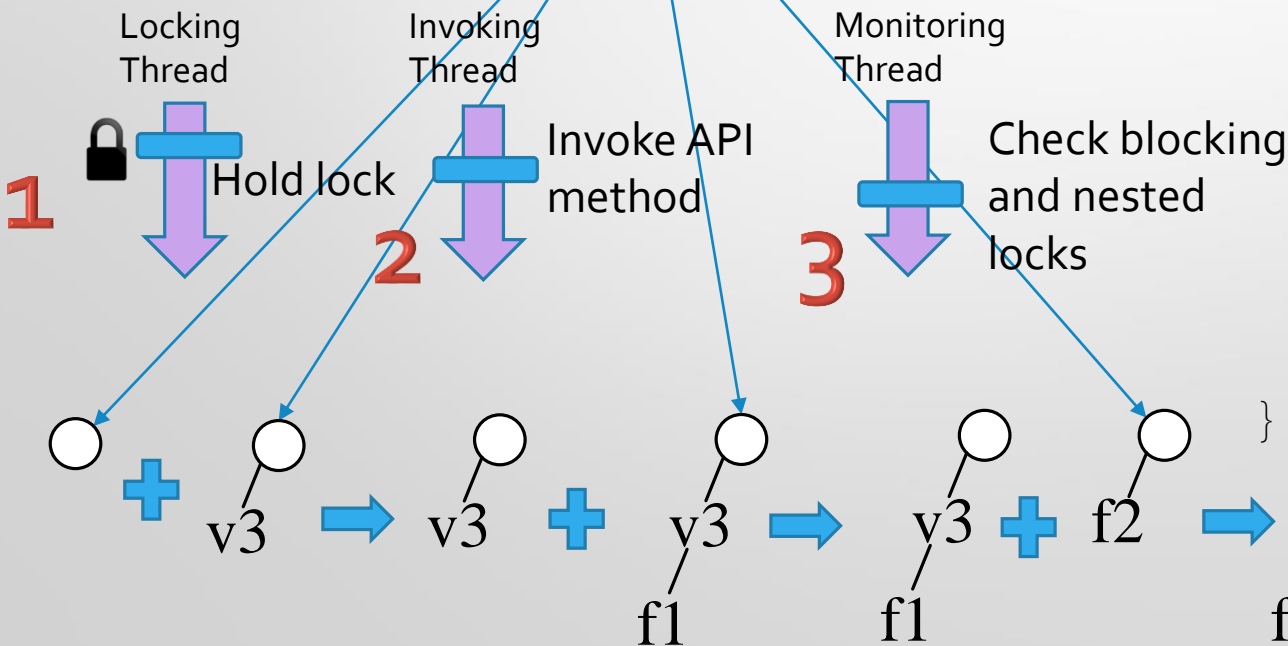

# Synthesizing Locking Structure

Locking candidates

- this
- v3
- f1
- f2

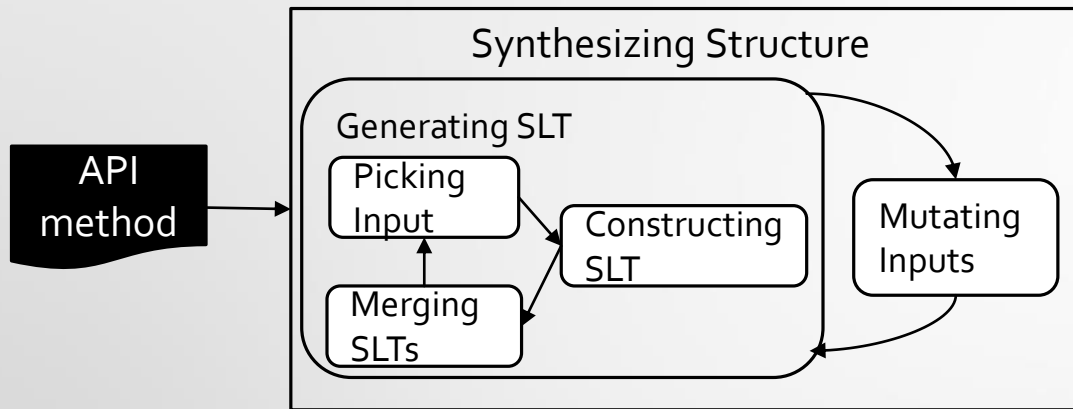

```
public class Example {  
    private Object f1;  
    private Object f2;  
  
    foo(int v1, boolean v2,  
        Object v3) {  
        synchronized(v3) {  
            synchronized(f1) {...}  
        }  
        synchronized(f2) {...}  
    }  
    getters and setters for  
    f1 and f2  
}
```

# Generating More SLTs

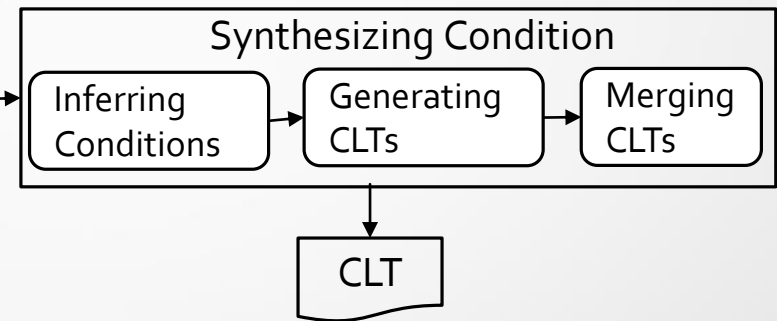

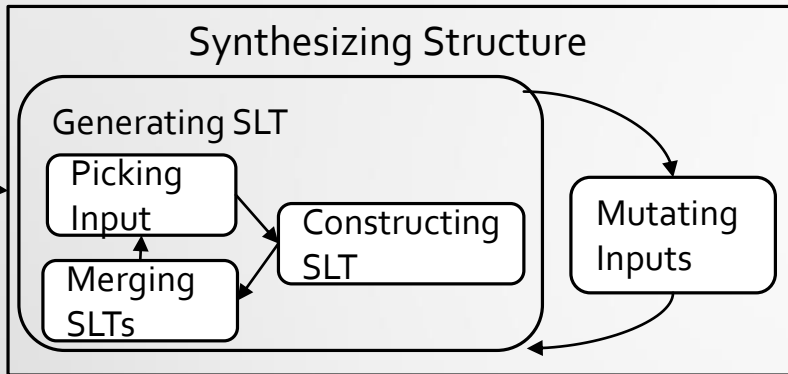

```
public class Example {
    private Object f1;
    private Object f2;

    foo(int v1, boolean v2,
        Object v3) {
        synchronized(v3) {
            if(v1<=0 || v2)
                synchronized(f1) {...}
        }
        synchronized(f2) {...}
    }
    getters and setters for
    f1 and f2
}
```

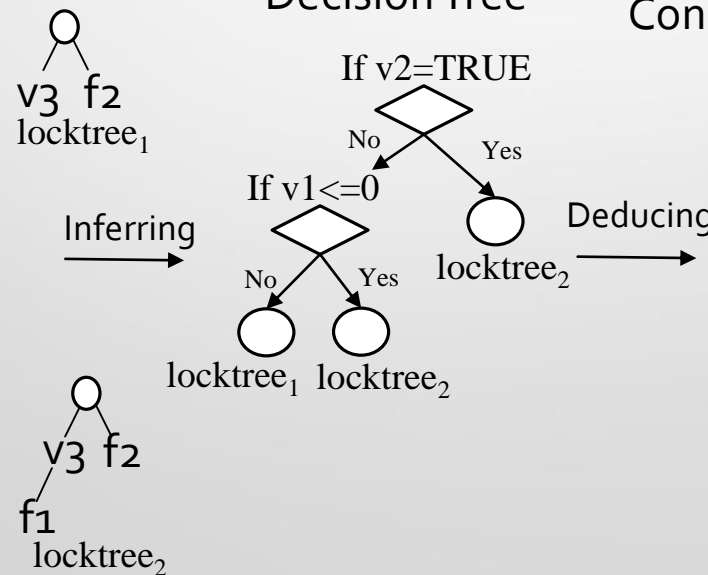

# Synthesizing Condition

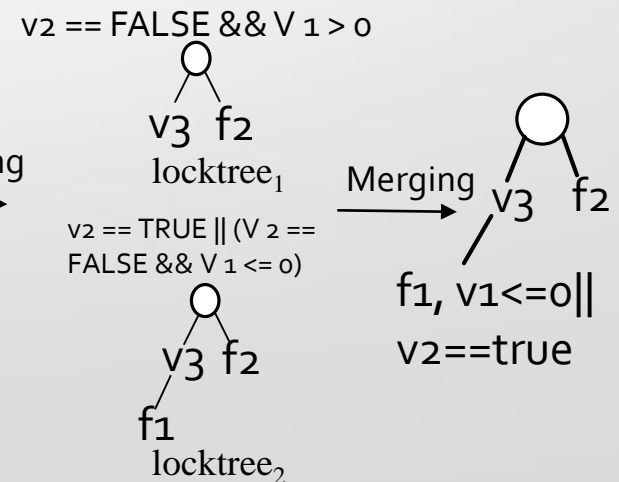

Encoded SLTs

| Attributes |       |    | Class                 |
|------------|-------|----|-----------------------|
| V1         | v2    | v3 |                       |
| -20        | FALSE | a  | locktree <sub>2</sub> |
| -1000      | TRUE  | a  | locktree <sub>2</sub> |
| 100        | TRUE  | a  | locktree <sub>2</sub> |
| 1          | FALSE | a  | locktree <sub>1</sub> |
| 89978      | FALSE | a  | locktree <sub>1</sub> |
| 9989776    | FALSE | a  | locktree <sub>1</sub> |
| 0          | TRUE  | a  | locktree <sub>2</sub> |
| 0          | FALSE | a  | locktree <sub>2</sub> |
| ...        |       |    |                       |

Decision Tree

Condition Lock Trees (CLT)

# Evaluation

- **RQ1.** How effective is LockPeeker in revealing locks in Java API methods ?
- **RQ2.** What kinds of deadlocks can be detected, if our detected latent locks are integrated ?
- **RQ3.** What is the significance of LockPeeker's threshold ?
- **RQ4.** What are the essential test instance variables that may trigger locks ?

# Evaluation: Subjects

| Project      | LOC            | M            | EM         | L            | EL         | Version  |
|--------------|----------------|--------------|------------|--------------|------------|----------|
| DBCP         | 5,792          | 6            | 6          | 6            | 6          | 1.2      |

| Xalan        | 12,039         | 23           | 13         | 24           | 13         | 2.7.2    |
| <b>Total</b> | <b>955,084</b> | <b>1,283</b> | <b>189</b> | <b>1,414</b> | <b>203</b> |          |

- Subjects are from our previous work [1]
- Searched “synchronized” keyword inside methods and manually checked locking objects to categorize them into 4 sets as we have talked previously
- We used 203 locks in the evaluation

# Evaluation

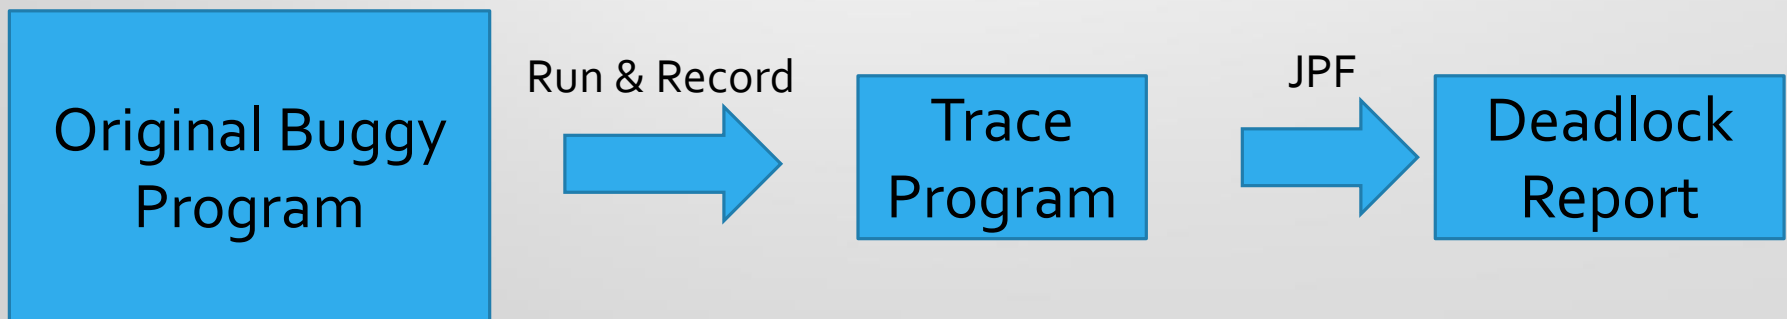

- **RQ1:** How effective is LockPeeker in revealing locks in Java API methods ?
- We manually compare the detected locks with the locks in API methods
  - The lock is detected
  - Relations among locks are detected
  - Branching specifications are detected
- $RC_1 = \text{strictly\_detected} / \text{total}$ ,  $RC_2 = \text{loosely\_detected} / \text{total}$

| Projects     | Parameter ( $S_{mp}$ ) |               |           | Field ( $S_f$ ) |               |           | Receiver ( $S_r$ ) |               |           | Total         |               |            |
|--------------|------------------------|---------------|-----------|-----------------|---------------|-----------|--------------------|---------------|-----------|---------------|---------------|------------|
|              | RC1                    | RC2           | #Locks    | RC1             | RC2           | #Locks    | RC1                | RC2           | #Locks    | RC1           | RC2           | #Locks     |

# Evaluation

- **RQ2:** What kinds of deadlocks can be detected, if our detected latent locks are integrated?
- Evaluation subject: 4 real-world deadlocks caused by latent locks
- Evaluation tool: deadlock detection tool CheckMate[2]
- CheckMate does not detect any deadlock alone, but detects all together with LockPeeker

# Evaluation

```
public class SimpleBirt287102 {
    private SimpleClassLoader loader;
    private Object obj;

    class Thread1 extends Thread {
        public void run() {
            synchronized(loader){
                Class.forName("java.lang.Object", true, loader);
            }
        }
    }

    class Thread2 extends Thread {
        public void run() {
            synchronized (obj) {
                synchronized(loader){
                    Class.forName("java.lang.Object", true, loader);
                }
            }
        }
    }

    class SimpleClassLoader extends ClassLoader {
        public Class<?> loadClass(String name) {
            synchronized (obj) {...}
            return super.loadClass(name);
        }
    }

    private static native Class<?> forName0(String name,
        boolean initialize, ClassLoader loader, Class<?> caller);
}
```

Run and Record

```
public class TraceProgram {
    static Object obj1 = new Object();
    static Object obj2 = new Object();
    static Thread t1 = new Thread(){
        public void run() {
            synchronized (obj2) {
                synchronized (obj1) {}
            }
        }
    };
    static Thread t2 = new Thread() {
        public void run() {
            synchronized (obj1) {
                synchronized (obj2) {}
            }
        }
    };

    public static void main(String[] args) {
        t1.start();
        t2.start();
    }
}
```

JPF

# Conclusion & Future Work

- Locks can be latent in API methods, which are not rare, but difficult to be detected
- LockPeeker dynamically checks latent locks from close-sourced Java API methods, even native methods which are implemented by other languages
- There are still many works need to take care in the future to detect latent locks in complicated methods:
  - Call sequences and inputs
  - Repeated locks
  - Complicated conditions
  - Missing the locks on objects in  $S_e$
